September 30, 2013

1 Surface albedo

Albedo is defined as the ratio of upwelling to downwelling radiative flux at the surface. The downwelling flux may be written as the sum of a direct and a diffuse component. Thus, two different albedos based on either the diffuse or direct flux component can be defined. White-sky albedo is defined as albedo in the absence of a direct component when the diffuse component is isotropic. Black sky albedo is defined as albedo in the absence of a diffuse component. While black sky albedo is a function of the solar zenith angle, white sky albedo is essentially zenith angle independent.

Within the shortwave radiation scheme, the reflection at the surface is handled considering both direct and diffuse downward radiation fluxes. For this, spectral albedos for parallel and diffuse radiation are needed. The spectral albedos distinguish between the visible ($0.3 - 0.7 \mu\text{m}$) and near-infrared ($0.7 - 5.0 \mu\text{m}$) spectral bands. Thus, 4 albedo values ($\alpha_{\text{dir}}^{\text{vis}}$, $\alpha_{\text{dir}}^{\text{nir}}$, $\alpha_{\text{diff}}^{\text{vis}}$, $\alpha_{\text{diff}}^{\text{nir}}$) are required for each grid point. The indices dir and diff indicate the type of radiation (direct or diffuse), whereas the indices vis and nir distinguish the spectral bands (UV-visible or near-infrared). In the following we will separately discuss snow-free land, snow-covered land, open water, sea-ice and fresh water lake points.

1.1 Albedo for diffuse downward radiation (white sky)

1.1.1 Snow-free land points

Over snow-free land, white sky surface albedos ($\alpha_{\text{diff}}^{\text{vis}}$, $\alpha_{\text{diff}}^{\text{nir}}$) are derived from monthly mean climatologies build from 16-days MODIS albedo over the year 2000-2003 (Schaaf *et al.*, 2002). Separate datasets are available for UV-visible and near-infrared spectral bands. The model does a linear interpolation between successive months, assuming that the monthly field belongs to the 15th of the month. The values are updated on a daily basis.

1.1.2 Snow-covered land points

The snow albedo for visible and near-infrared spectral bands is calculated by

$$\alpha_{\text{diff}}^{\text{vis}} = \alpha_{\text{diff}}^{\text{nir}} = \alpha_{s,\text{min}} + S_{\text{age}} (\alpha_{s,\text{max}} - \alpha_{s,\text{min}}) , \quad (1)$$

with $\alpha_{s,\text{max}} = 0.85$ and $\alpha_{s,\text{min}} = 0.5$. The reduction of snow albedo with increasing snow age is taken into account by an ageing function $0 \leq S_{\text{age}} \leq 1$. The value of S_{age} is 1 for fresh snow and approaches 0 for old snow. The variation of S_{age} with time consists of a constant ageing and a regeneration by falling snow:

$$\Delta S_{\text{age}} = S_{\text{age}} \left[\frac{P_{\text{snow}}}{P_{\text{norm}}} - \frac{\Delta t}{\tau_a} \right] \quad (2)$$

P_{snow} is the snowfall rate, and $P_{\text{norm}} = 5 \text{ mm}/24 \text{ h}$. If no snow exists, $S_{\text{age}} = 1$ is prescribed. Note that for needleleaved and broadleaved forests snow ageing is not taken into account and the snow albedo is limited to values of about 0.3.

1.1.3 Open-water points

For open-water points, the white sky albedos are set to a constant value.

$$\alpha_{\text{diff}}^{\text{vis}} = \alpha_{\text{diff}}^{\text{nir}} = 0.07 \quad (3)$$

1.1.4 Sea-ice points

The ice surface albedo for diffuse radiation is approximated as:

$$\alpha_{\text{diff}}^{\text{vis}} = \alpha_{\text{diff}}^{\text{nir}} = \alpha_{i,\text{max}} - (\alpha_{i,\text{max}} - \alpha_{i,\text{min}}) \exp \left[-C_\alpha \left(\frac{\theta_{f0} - \theta_i}{\theta_{f0}} \right) \right], \quad (4)$$

where $\alpha_{i,\text{max}} = 0.7$ and $\alpha_{i,\text{min}} = 0.43$ are maximum and minimum values of the sea-ice albedo, $\theta_{f0} = 273.25$ K is the fresh water freezing point, θ_i is the ice surface temperature and $C_\alpha = 95.6$ is a fitting coefficient. Equation 4 is meant to implicitly account (in a crude way) for the seasonal changes of α . The ice albedo is the lower the warmer, and therefore wetter the ice is.

1.1.5 Fresh water lake points

For frozen lakes, equation 4 is used, too. However, the maximum and minimum ice albedo is set to $\alpha_{i,\text{max}} = 0.6$ and $\alpha_{i,\text{min}} = 0.1$, respectively. If no ice is present, the surface albedo for diffuse radiation is approximated as

$$\alpha_{\text{diff}}^{\text{vis}} = \alpha_{\text{diff}}^{\text{nir}} = 0.07 \quad (5)$$

1.2 Albedo for direct downward radiation (black sky)

While surface albedo for the diffuse flux does not depend on the solar zenith angle μ , surface albedo for the direct flux does (Yang *et al.*, 2008). The formula for taking into account the zenith angle dependency has been taken over from the Ritter-Geleyn radiation scheme. It is applied, irrespective of the underlying type of surface.

$$\alpha_{\text{dir}}^{\text{vis}} = \frac{1.0 + 0.5 \cos(\mu) \left(\frac{1}{\alpha_{\text{diff}}^{\text{vis}}} - 1 \right)}{\left[1.0 + \cos(\mu) \left(\frac{1}{\alpha_{\text{diff}}^{\text{vis}}} - 1 \right) \right]^2} \quad (6)$$

$$\alpha_{\text{dir}}^{\text{nir}} = \frac{1.0 + 0.5 \cos(\mu) \left(\frac{1}{\alpha_{\text{diff}}^{\text{nir}}} - 1 \right)}{\left[1.0 + \cos(\mu) \left(\frac{1}{\alpha_{\text{diff}}^{\text{nir}}} - 1 \right) \right]^2} \quad (7)$$

Note that the surface albedo for the direct flux is derived from the surface albedo for the diffuse flux, which is clearly an approximation. Also note that the parameterization is applied separately for the UV-visible and near-infrared spectral bands.

1.3 Sample plots

Figure 1 and 2 show white sky and black sky albedo for the 4th Jan 2012 00UTC as used by ICON.
